

# Asset Level Modelling of RISKS In the Face of Climate Induced Extreme Events and ADAPTtation (RISKADAPT)

Climate data and climate change

Risk assessment of structures under Climate Change

Athens

23/10/2025

Framework Programme of the EU

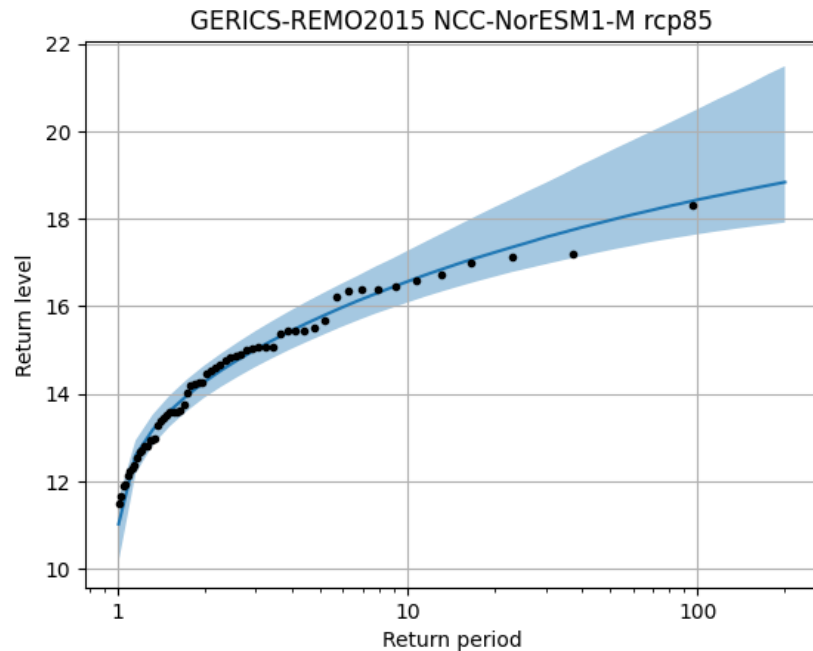

# RISKADAPT pilot cases

- Pilot 1 - Polyfytos Road Bridge in Region of Western Macedonia, Greece.
  - Climate forcing: Precipitation and river discharges.
- Pilot 2 - Energy transmission grid in a Nordic climate.
  - Climate forcing: Icing and snow load.
- Pilot 3 - Cattinara hospital building in Trieste, Italy.
  - Climate forcing: strong Bora winds.
- Pilot 4 - High-rise buildings with glass facades in Hong Kong.
  - Climate forcing: heavy wind and rain.

# Climate extremes

- Extreme value analysis gives statistical tools to evaluate occurrence probabilities of rare events based on historical or simulated future time series of maxima.
- In rapidly changing climate, the non-stationary nature of the system must be accounted.

# Climate extremes - generalized extreme value distribution GEV

The GEV distribution is defined by three parameters:  $\mu$ ,  $\sigma$  and  $\xi$ :

$$G(y; \mu, \sigma, \xi) = \exp\left(-\left[1 + \xi \left(\frac{y-\mu}{\sigma}\right)_+^{-\frac{1}{\xi}}\right]^{-\frac{1}{\xi}}\right),$$

*GEV cumulative distribution*

which gives quantiles defined by tail probabilities  $p$

$$y_p = \begin{cases} \mu - \frac{\sigma}{\xi} [1 - \{-\log(1-p)\}^{-\xi}], & \text{for } \xi \neq 0, \\ \mu - \sigma \log\{1 - \log(1-p)\}, & \text{for } \xi = 0. \end{cases}$$

*GEV quantiles*

For non-stationarity, we can let the parameters depend on external factors, for example as in

$$\mu_t = \mu_0 + \mu_{trend} \cdot (t - t_0) + f(t) + \epsilon_t.$$

Our analysis is based on hierarchical Bayesian statistics and MCMC algorithms implemented in Stan statistical language and Python.

# ERA5 reanalysis for historical and the current climate

- **ERA5** is the fifth generation ECMWF reanalysis for the global climate and weather for the past 8 decades.
- It is the best source for global historical analysis of the actual weather based on numerical weather prediction model and wide range of observations.
- Available from 1940 to present.
- Accessible from Copernicus Climate Store (CDS), Google cloud, etc.

with return period of 20 years.  
Current climate

# Climate modelling

- Climate models are vast computer simulations that numerically solve physics and chemistry equations.
- A numerical description of the climate system, its components, the connections between different parts, and external forcing run on supercomputers.
- Models are used not only to examine future developments but also to enhance the basic understanding of the climate system.
- Concentration scenarios explore different possible futures.
- Climate models use these scenarios to produce climate projections. Climate projections help assess the impacts and risks of climate change.
  
- RISKADAPT utilises model data available from CDS: the model intercomparison projects, such as **CMIP6** and **Euro-CORDEX**.
- In addition, high resolution **Harmonie-CLIM** model is used over Fenno-Scandinavia.

# Climate modelling: challenges and sources of uncertainties

Figure: IPCC (2007)

# Estimating local changes – temperature

## b) Annual mean temperature change (°C) relative to 1850-1900

Across warming levels, land areas warm more than oceans, and the Arctic and Antarctica warm more than the tropics.

Simulated change at 1.5 °C global warming

Simulated change at 2 °C global warming

Simulated change at 4 °C global warming

Figure: IPCC

# Estimating local changes – precipitation

## c) Annual mean precipitation change (%) relative to 1850-1900

Precipitation is projected to increase over high latitudes, the equatorial Pacific and parts of the monsoon regions, but decrease over parts of the subtropics and in limited areas of the tropics.

Simulated change at 1.5 °C global warming

Simulated change at 2 °C global warming

Simulated change at 4 °C global warming

Relatively small absolute changes may appear as large % changes in regions with dry baseline conditions

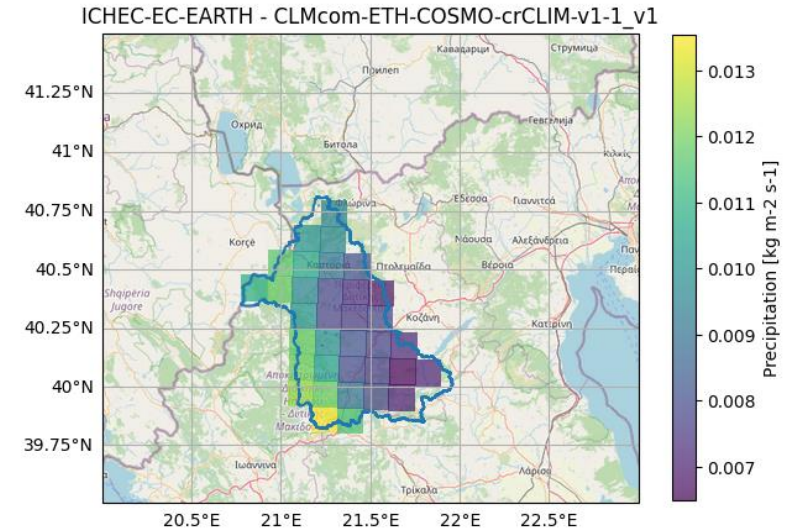

Figure: IPCC

# RISKADAPT Pilot 1 – Polyfytos road bridge

- Hydrological and hydrodynamical modelling by University of Ljubljana based on estimated changes if precipitation.
- Intensity–duration–frequency analysis for Euro-CORDEX model simulations.

# RISKADAP Pilot 2 - icing in Fenno-Scandinavia

- Ice and snow loads of transmission towers.
- Structural risks analysis by ERRA.
- Corona losses in power transmission.
- Effects on wind power production.
- High-resolution Harmonie CLIM model.
